ABSTRACT
Purpose To report a modified preparation and to systematically study the structure, magnetic and other properties of γ-Fe₂O₃-DMSA-DG NPs (2-deoxy-D-glucose (2-DG) conjugated meso-2,3-dimercaptosuccinic acid coated γ-Fe₂O₃ nanoparticles) and test its ability to improve Hela tumor cells targeting in vitro compared to the γ-Fe₂O₃-DMSA NPs.

Methods The conjugation of 2-DG on the surface of γ-Fe₂O₃-DMSA NPs was performed by esterification reaction and characterized. Acute toxicity was evaluated using MTT assay. Cellular uptake was investigated by Prussian blue staining and UV colorimetric assay.

Results DG was successfully functionalized onto the surface of γ-Fe₂O₃-DMSA NPs; binding efficiency was ~60%. The mean diameter of single core of γ-Fe₂O₃-DMSA-DG NPs was 10 nm. Particle size and polydispersity index of its aggregates were 156.2 nm and 0.162, respectively. 2-DG-conjugated nanoparticles caused little cytotoxic effects on Hela cells at the concentration range of 0–600 μg/mL. When 2-DG-conjugated and non-conjugated nanoparticles were incubated with Hela cells for 4, 8 and 12 h, the 2-DG-conjugated nanoparticle showed significant amount of uptake in cells compared to their non-targeted counterparts.

Conclusion γ-Fe₂O₃-DMSA-DG NPs could be developed as a tumor-targeted probe for cervical cancer imaging and therapy.

INTRODUCTION

Tumor cells have acquired metabolic abilities to survive under unfavorable microenvironment conditions thus developing a more aggressive phenotype. Increased glucose utilization is one of the most characteristic and early-recognized biochemical markers of the transformed phenotype (1). Therefore, some researchers have proposed the glucose transporter (GLUT) as an important diagnostic and therapeutic target to modulate the accelerated tumor growth (2,3). GLUT activity in mammalian cells has been monitored by radiolabeled tracers such as [14C] 2-deoxy-D-glucose, [18F] fluoro-2-deoxy-D-glucose, and [14C] or [3H]3-O-methyl-D-glucose (4–7). [18F] fluoro-2-deoxy-D-glucose (18F-FDG) is the most common radiotracer of increased glucose metabolism to visualize tumor activity and location with positron emission tomography (PET) in the clinical setting. The method is sensitive and quantitative (4,8). For many high throughput preclinical studies, however, 18F-FDG is impractical due to the short half-life of the isotope. Therefore, alternatives to 2-deoxy-D-glucose (2-DG) labeled imaging agents would be valuable. Among the imaging modalities, magnetic resonance imaging (MRI) is a powerful medical diagnostic imaging technique for soft tissue imaging (9). Other advantages of MRI include the use of nonionizing radiation, high sensitivity and higher specificity, multiplanar imaging capability, and high anatomical resolution. Superparamagnetic iron oxide nanoparticles (SPIO NPs, Fe3O4 or γ-Fe2O3) are one of the most adopted magnetic nanoprobes for T2 weighted MRI studies. In addition, especially in the last decade, the field of biomedicine witnessed an explosion of interest in the use of magnetic nanomaterial in magnetic cell labeling and sorting, effective treatment of some diseases, such as anti-tumor drug and gene delivery and guided hyperthermia therapy (10–18).

For a novel targeted magnetic nanoparticles based on higher glucose consumption of tumor cell, we reported preparation, transmission electron microscopy (TEM) and infrared spectroscopy (IR) characterization of a novel 2-preparation, transmission electron microscopy (TEM) and on higher glucose consumption of tumor cell, we reported preparation, transmission electron microscopy (TEM) and infrared spectroscopy (IR) characterization of a novel 2-

MATERIALS AND METHODS

Materials

meso-2, 3-dimercaptosuccinic acid (DMSA) was purchased from Shanghai Beihe Chemicals Co. Ltd, China. D-Glucosamine (2-amino-2-deoxy-D-glucose) hydrochloride (ADG-HCl) was purchased from Alfa Aesar GmbH & Co. KG. 1-Ethyl-(3-3-dimethylaminopropyl) carbodiimide hydrochloride (EDC) and N-hydroxysuccinimide (NHS) were purchased from Pierce Chemical Co. Human cervical cancer cells (Hela) were purchased from Shanghai Cellular Institute of China Scientific Academy. RPMI 1640 medium (containing 10% fetal calf serum, 100 μg/mL penicillin, and 100 μg/mL streptomycin), glucose-free RPMI 1640 medium and fetal calf serum were purchased from BoooCle BioTech Co., Ltd. GLUT1 antibody was purchased from Shengyan Biomedicals (Shanghai) Co., Ltd. The other chemicals were analytical grade reagents and purchased from Shanghai Chemical Reagent Corporation, China. All chemicals were used as received. Double distilled water was used for all the experiments. Dialysis tubing (MW: 8000–10000) was purchased from Nanjing Geneime Biotechnology Co., LTD.

Synthesis of γ-Fe2O3-DMSA-DG NPs

γ-Fe2O3 NPs were synthesized by chemical co-precipitation and subsequently stabilized with DMSA as described earlier (20). Briefly, a 200 mL mixed solution of FeCl3·6H2O (0.01 M) and FeSO4·7H2O (0.006 M) at pH 1.7 was prepared under a stream of N2 protecting. Then, aqueous ammonia solution (1.5 M) was dropped into it with violently stirring until the pH of the solution was raised to 9. The balanced equation was as follows:

\[
\text{Fe}^{3+} + 2\text{Fe}^{3+} + 8\text{OH}^- \rightarrow \text{Fe}_3\text{O}_4 + 4\text{H}_2\text{O}
\]

The obtained magnetite was washed immediately with water for 5 times and ethanol for 2 times by magnetic separation. Then, the Fe3O4 NPs were dispersed in water with a mass concentration of 3 mg/mL and its pH was adjusted to 3.0 using 0.1 M HCl. Then theses Fe3O4 NPs were oxidized into reddish-brown γ-Fe2O3 NPs using air for 1 h at about 95–100°C. Subsequently, the γ-Fe2O3 NPs
were coated with DMSA according to the process described elsewhere (21,22). Finally, the products were washed repeatedly with water and enriched with the help of a magnet.

The immobilization of 2-DG on γ-Fe₂O₃-DMSA NPs via esterification reaction was according to the process reported with modification (19). Surface activation was performed by exposing the acid surface to EDC (0.5 mM) and NHS (2.5 mM). For improving the conjugation efficiency, EDC (0.5 mM) and NHS (2.5 mM) were added for three times with 1 mL per time into 10 mL γ-Fe₂O₃-DMSA NPs (1 mM). The mixed solution was left at room temperature for 30 min. Add 10 mL of ADG-HCl (final concentration: 2 mg/mL) to 20 mL solution above. React for 2 h at room temperature. Purify by dialysis overnight against water (dialysis tubing, MW: 8000–10000).

Cell Culture, Cytotoxicity and Uptake Experiments

Hela cells were cultured in RPMI 1640 medium containing 10% fetal calf serum (FCS), 100 μg/mL penicillin, and 100 μg/mL streptomycin. For control experiments, medium having no particle was used. The cells were incubated at 37°C in 5% CO₂ atmosphere and medium was replaced every third day.

The cytotoxicity of γ-Fe₂O₃-DMSA-DG NPs was evaluated by using a 3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyl tetrazolium bromide (MTT) assay. The Hela cells were grown in 96-well plates at 5×10⁴ cells per well at 37°C in 5% CO₂ atmosphere for 24 h. The culture medium was replaced with 100 μL of medium containing 0–600 μg/mL of nanoparticles. The cytotoxicity was evaluated by determining the viability of Hela cells. After incubation for 24 h, the medium was removed and rinsed once with medium, MTT dye solution (5 mg/mL) was added to each well. After 4 h of incubation at 37°C, the medium was removed and Formazan crystals were dissolved in 200 μL dimethylsulphoxide (DMSO) and quantified by measuring the absorbance of the solution by a microplate reader (Ultra Microplate Reader EL×808 IU, Bio-RAD) at 570 nm. The viability was calculated as the percentage of control (cells receiving no treatment).

In the cell-uptake experiments, cells were washed with PBS and medium was changed to glucose-free RPMI 1640. The dilutions of γ-Fe₂O₃-DMSA NPs and γ-Fe₂O₃-DMSA-DG NPs were added for the concentration, time and temperature indicated. For Prussian blue staining, which indicates the presence of iron, one part of the cells was fixed with 2.5% glutaraldehyde and potassium thiocyanate was added to this solution to form the iron-thiocyanate complex. 150 μL of the mixture was transferred to a 96-well plate and the absorbance was read after 10 min at 480 nm using a microplate reader (Model 680, Bio-RAD) (23). A standard curve using the differently

Characterization

TEM studies and electron diffraction (ED) were carried out using a JEM-2000EX (Jeol, Japan). A drop of particles suspension in water was placed on a carbon-coated copper grid (300 mesh), followed by drying the sample at room temperature before it is attached to the sample holder on the microscope. The structure of the crystal was determined from its ED.

The functional groups present in the powder samples of ADG-HCl, DMSA, γ-Fe₂O₃-DMSA NPs and γ-Fe₂O₃-DMSA-DG NPs were identified by fourier transform infrared (FTIR) spectroscopy. FTIR spectra were recorded on a Nicolet Nexus 870 FTIR spectrometer ( Nicolet, USA) and 1% of the powder samples were mixed and ground with 99% KBr. Discs of 10 mm diameter were prepared by pressing the powder mixture at a load of 10 tons under vacuum for 2 min and the spectrum was taken in the range of 4000-400 cm⁻¹ with a resolution of 2 cm⁻¹ at room temperature.

The elemental analysis and 2-DG loading on γ-Fe₂O₃-DMSA NPs were measured by energy dispersive X-ray spectroscopy (EDX). The thermal behaviour of the powders was studied by thermal gravimetric analysis (TGA) using a Perkin-Elmer TGA 7 Thermogravimetric Analyzer in synthetic N₂ atmosphere up to 700°C.

Magnetic measurements were carried out with a Lakeshore 7470 vibrating sample magnetometer (VSM) (Lakeshore, 7407 VSM system). The samples were dried by heating at 80°C.

The hydrodynamic diameter and size distribution of the particles were determined at 25°C by photon correlation spectroscopy (PCS) instrument (Malvern Zetasizer 3000, Malvern Instruments Co.). The zeta potential was obtained by measuring the electrophoretic mobility (Malvern Zetasizer 3000, Malvern Instruments Co.). All samples were diluted 100 times by water.
FeCl₃·6H₂O solution was recorded in the same conditions to quantify the amount of cell-bound iron. Each experiment was repeated in triplicate wells at least three times. Means and standard deviations were calculated.

To determine the competitive effect and specificity of glucose, Hela cells were incubated at 37°C with 2 μg/mL anti-GLUT1 antibody before γ-Fe₂O₃-DMSA NPs or γ-Fe₂O₃-DMSA-DG NPs were added. NPs were added to a final concentration of 100 μg/mL and cells were incubated at 37°C for another 2 h. SPIO NPs in cells were stained with Prussian blue as described above.

MRI

To evaluate the potential of SPIO NPs in clinical MR imaging, labeled Hela cells after incubation 2 h were trypsinized, centrifuged, counted, and resuspended in 2% agarose in Eppendorf tubes. MRI was performed at 1.5 T (Siemens Anantos 1.5 T System) for T₂ weighted imaging (T₂WI) by using a fast spin-echo sequence (repetition time/echo time (TR/TE), 5500 ms/100 ms; field of view (FOV), 50 mm × 50 mm; slice thickness, 3 mm; matrix, 256×256) and a 16-echo sequence (TR/TE, 3000 ms/22 ms, 44 ms, 66 ms, 88 ms, 110 ms, …… 352 ms; FOV, 50 mm × 50 mm; slice thickness, 3 mm; matrix, 256×256) at room temperature. The signal intensities of the nonlabeled and γ-Fe₂O₃-DMSA NPs or γ-Fe₂O₃-DMSA-DG NPs–labeled cells were determined from a circular 10-mm² region of interest (ROI).

RESULTS

Synthesis of γ-Fe₂O₃-DMSA-DG NPs

The γ-Fe₂O₃ NPs were synthesized by chemical coprecipitation and stable nanoparticles suspension was obtained via surface coating with DMSA. Over amount of FeSO₄·7H₂O was required in this reaction in order to prevent possible oxidation of Fe²⁺. Then the pH of mixed solution was adjusted to 9 using aqueous ammonia solution in order to make sure black Fe₃O₄ was precipitated absolutely. There are two theories to explain the possible mechanism of binding of DMSA to SPIO NPs. One theory is strong coordinate bonds between Fe and S of DMSA were formed (24). The other theory is coordinate bonds between Fe and COOH of DMSA were formed (25). For conjugating 2-DG to the surface of nanoparticles, surface acylamidation reaction was introduced in this paper outlined in Fig. 1. This surface reaction allows the formation of carboxylic acid groups on the γ-Fe₂O₃-DMSA NPs surface that, once activated with EDC, are competent for reacting with primary amino groups on the 2-DG.

Characterization

The TEM images of γ-Fe₂O₃-DMSA NPs and γ-Fe₂O₃-DMSA-DG NPs are shown in Fig. 2, which shows that most of the particles are quasi-spherical and the average diameter of single core of NPs are 10 nm. The particle aggregates are well dispersed in water in both Fig. 2 (a) and (b). Under conditions of room temperature and air-induced oxidation, γ-form of Fe₂O₃ core was the only possible crystal structure produced. Other crystal structure, for example, α-Fe₂O₃ NPs were not produced because the phase transition of γ-Fe₂O₃ to α-Fe₂O₃ occurred at the temperature range of 580–608°C in the dependence on the particle size (26). ED measurements were also performed to confirm the crystal form of γ-Fe₂O₃-DMSA-DG NPs prepared. The result is shown in Fig. 2(c). Each diffraction ring coincides with the diffraction ring of γ-Fe₂O₃ reported (27,28).

Qualitative characterization of γ-Fe₂O₃-DMSA-DG NPs was achieved by SEM/EDS and FTIR. Figure 3a
demonstrates that DG are successfully functionalized onto the surface of γ-Fe2O3-DM
ta NPs as evidenced in the FTIR spectra of γ-Fe2O3-DM
ta NPs and γ-Fe2O3-DM
ta-DG NPs. The FTIR data of ADG-HCl, DMSA, γ-Fe2O3-DM
ta NPs and γ-Fe2O3-DM
ta-DG NPs are listed in Table I. The band at 1088 and 1052 cm⁻¹ in the FTIR curve of γ-
Fe2O3-DMSA NPs corresponded to C-N and C-O stretching vibration of 2-DG, respectively. Thus, IR results confirm the successful surface 2-DG functionalization of γ-Fe2O3-DM
ta NPs.

Figure 3b shows a typical SEM/EDS elemental analysis of γ-Fe2O3-DM
ta NPs and γ-Fe2O3-DM
ta-DG NPs. From the peak area of N, the atomic ratio of N was
increased from 0 to 4.97% after conjugation of 2-DG on the
surface of γ-Fe2O3-DMSA NPs. This also indicated 2-
DG was successfully functionalized onto the surface of γ-
Fe2O3-DMSA NPs.

TGA has been performed to confirm the coating forma-
tion and estimate the binding efficiency of DMSA and 2-DG
on the surface of γ-Fe2O3-DMSA NPs, attributed to decomposition of DMSA, is
4.95%, corresponding to the molar ratio between the Fe
and DMSA (100:2.5) or the number ratio between Fe2O3
and DMSA (1:516). The calculation was as follows:

the number ratio between Fe2O3 NPs and DMSA in γ

\[
\text{Fe}_2\text{O}_3 - \text{DM} \text{S}A \text{ NPs system} = \frac{3(1 - W_{\text{DM} \text{S}A\%}) - W_{\text{W}2\%}}{4\pi\rho R^3 N_A} : \frac{W_{\text{W}1\%}}{M_1} = 1 : 516
\]

where \(W_{\text{W}1\%}\) is weight loss percentage of DMSA of γ-Fe2O3-DM
ta NPs, \(W_{\text{W}2\%}\) is weight loss percentage of water in γ-Fe2O3-DM
ta NPs sample, \(\rho\) is the density of Fe2O3, \(R\) is the radius of Fe2O3 nanoparticle, \(M_1\) is molecular weight of DMSA, \(N_A\) is Avogadro’s number.

The weight loss for γ-Fe2O3-DM
ta-DG NPs between 250 and 600°C is increased to 9.31%, mainly due to the decomposition of DMSA and ADG. Assuming the weight for γ-Fe2O3 NPs in the Fig. 4 (a) and (b) is 86.86% and 75.23% respectively, and according the molecular weight of DMSA and ADG is 182.2 and 179.1 respectively, we could calculate the molar ratio between DMSA and ADG (1 : 1.2) in the γ-Fe2O3-DM
ta-DG NPs system. The calculation was as follows:

the molar ratio between DMSA and ADG in the γ

\[
\text{Fe}_2\text{O}_3 - \text{DM} \text{S}A - \text{DG} \text{ NPs system} = \frac{W_{\text{DM} \text{S}A\%} - \frac{(1 - W_{\text{DM} \text{S}A\%})W_{\text{W}1\%}}{1 - W_{\text{DM} \text{S}A\%} - W_{\text{W}2\%}}}{M_2} : \frac{(1 - W_{\text{DM} \text{S}A\%})W_{\text{W}1\%}}{1 - W_{\text{DM} \text{S}A\%} - W_{\text{W}2\%}} = 1 : 1.2
\]

where \(W_{\text{W}1\%}\) is weight loss percentage of DMSA and ADG of γ-Fe2O3-DM
ta-DG NPs, \(W_{\text{W}2\%}\) is weight loss percentage of water in γ-Fe2O3-DM
ta-DG NPs sample, \(M_2\) is molecular weight of ADG. Considering that DMSA is a compound with two carboxyl groups, the binding efficiency of 2-DG on the surface of γ-Fe2O3-DM
ta NPs is about 60% (carboxyl group:2-DG=10:6).

The hysteresis loop of the as-synthesized magnetic NPs is shown in Fig. 5, which is measured at room temperature with a VSM. Magnetic measurements indicated superparamagnetic behavior at room temperature for both samples, as evidenced by zero coercivity and remanence on the magnetization loops. The saturation magnetization value (Ms) for γ-Fe2O3-DM
ta NPs and γ-Fe2O3-DM
ta-DG NPs was 48.95 and 49.67 emu/g, respectively. The Ms of both NPs was similar to the value reported previously (29,30) and enough to be used as MRI probe. It can be concluded there was no significant reduction of the Ms after conjugation reaction.

The dispersion in water of γ-Fe2O3-DM
ta NPs and γ-
Fe2O3-DM
ta-DG NPs produced nanoparticle aggregates. PCS was applied to determine the average hydrodynamic diameter and polydispersity index of these aggregates. The
average hydrodynamic diameter (the mean diameter based upon the intensity of scattered light) of γ-Fe₂O₃-DMSA NPs and γ-Fe₂O₃-DMSA-DG NPs was 154.6±28.3 and 156.2±28.2 nm, respectively, which was the total diameter of aggregates and its aqueous layer thickness. The polydispersity index is a ratio that gives information about the homogeneity of the particle size distribution in a given system. In this paper, polydispersity index was applied to evaluate the monodisperse population of particle aggregates. The zeta potential of γ-Fe₂O₃-DMSA NPs and γ-Fe₂O₃-DMSA-DG NPs was (-21.76±0.80) and (-10.22±0.81) mV, respectively. This decrease in surface negative charge was due to the absence of some carboxyl groups on the surface of γ-Fe₂O₃-DMSA-DG NPs after conjugation of ADG to these carboxyl groups. The polydispersity index of γ-Fe₂O₃-DMSA NPs and γ-Fe₂O₃-DMSA-DG NPs was 0.146 and 0.162, respectively. Considering no significant difference of particle size and distribution between γ-Fe₂O₃-DMSA NPs and γ-Fe₂O₃-DMSA-DG NPs was detected, it suggested that no bigger aggregates generated during conjugation reaction.

MTT Cytotoxicity Assay

To examine the acute toxicity of γ-Fe₂O₃-DMSA NPs and γ-Fe₂O₃-DMSA-DG NPs, the viability of Hela cells incubated with the nanoparticles at the concentration range of 0–600 μg/mL was evaluated using the MTT assay (Table II). The result demonstrates that a dose-dependent reduction in MTT absorbance for Hela cells incubated with non-conjugated nanoparticles and 2-DG-grafted nanoparticles at all tested concentrations. In all concentration range, they showed little cytotoxic effects to Hela cells and the cells remained more than 80% viable relative to control. And the cytotoxicity of γ-Fe₂O₃-DMSA-DG NPs was lower than that of γ-Fe₂O₃-DMSA NPs. There were no statistically significant differences in the concentration range of 50–600 μg/mL between viability values of the two groups (p>0.05).

Cellular Uptake

Cellular uptake of γ-Fe₂O₃-DMSA NPs and γ-Fe₂O₃-DMSA-DG NPs was investigated in Hela cells. To visualize the iron within SPIO NPs labeled cells, Prussian blue staining was performed. Fig. 6 shows the optical micrographs of Prussian blue stained Hela cells after 2 h incubation with 100 μg/mL SPIO NPs. It can be seen that most of the Hela cells incubated with SPIO NPs were stained in blue and no blue spots were observed in the cytoplasm of the control cells without SPIO NPs under the same conditions. And the number of blue spots in Hela cells incubated with γ-Fe₂O₃-DMSA-DG NPs was more than that in the cells incubated with γ-Fe₂O₃-DMSA NPs. Specificity of glucose was also evaluated by competitive binding method. Dependence of SPIO NPs uptake on GLUT family transporters was tested by the addition of the indicated quantities of anti-GLUT1 antibody prior to incubation with SPIO NPs. The results are shown in Fig. 6 (c) and (d). The inhibition phenomena showed exposure of the cells to GLUT1 antibody prior to treatment with 2-DG-grafted NPs significantly eliminated blue spots. Comparatively, non-targeted NPs were not blocked by GLUT1 antibody.

UV colorimetric assay was also utilized to quantify the cellular uptake of γ-Fe₂O₃-DMSA NPs and γ-Fe₂O₃-DMSA-DG NPs into Hela cells in terms of iron concentration. The results shown in Table III demonstrate the specificity of the 2-DG-grafted nanoparticles for the glucose transporter. The uptake of 2-DG-conjugated and non-conjugated nanoparticles by Hela cells was time dependent and increased with time. When the materials were incubated with cells for 4, 8 and 12 h, the 2-DG-grafted nanoparticles showed significant amount of uptake in Hela cells compared to their non-targeted counterparts. Following 4–12 h in culture, the Hela cells incubated with γ-Fe₂O₃-DMSA-DG NPs demonstrated an uptake approximately 1.93–5.25 times higher than the γ-Fe₂O₃-DMSA NPs group with 50–200 μg/mL. This might be due to the high glucose consumption.

MRI

Using a clinical 1.5-T MR scanner, the MRI signal intensity of Hela cells in agarose incubated with SPIO NPs (Fig. 7 (c) and (d)) was significantly decreased (a significant darkening of T₂W signals) compared with water and nonlabeled cells (Fig. 7 (a) and (b)) (no MR contrast). γ-Fe₂O₃-DMSA NPs and γ-Fe₂O₃-DMSA-DG NPs caused noticeable shorter T₂ relaxation times with signal loss in the cells. Mean T₂ relaxation time of γ-Fe₂O₃-DMSA NPs and γ-Fe₂O₃-DMSA-DG NPs internalized Hela cells was 670.6 ± 26.7 and 233.0 ±
9.3 ms, respectively. No changes in $T_2$ relaxation time were observed in water and nonlabeled cells.

**DISCUSSION**

Many tumors have been shown to overexpress facilitated glucose transporters. $^{18}$F-FDG demonstrates functional imaging at the cellular level, where elevated glucose consumption by malignant cells results in increased uptake of $^{18}$F-FDG compared with normal tissue. SPIO NPs hold promise as multifunctional constructs for use in early cancer detection and treatment. If SPIO NPs could be conjugated with glucose analog, a nontoxic tracer for rapid tumor detection, SPIO NPs would potentially be used in various fields of biomedical research, and maybe even clinical applications. In this study, we successfully synthesized 2-deoxy-D-glucose conjugated $\gamma$-Fe$_2$O$_3$-DMSA NPs by a modified preparation method under very mild conditions without the need of high temperature, organic solvent, surfactant and some other special experimental technology, such as DMSO was commonly used as solvent (31) in this reaction system and was difficult to remove from the solution of SPIO NPs. EDC, as a zero-length crosslinking agent, reacts with carboxyl group of DMSA to form a primary amine-reactive $O$-acylisourea intermediate. In the presence of NHS, EDC can be used to convert carboxyl groups to amine-reactive NHS esters. The bending efficiency was about 40% in our previous paper (data no shown) (19). The process of adding EDC and NHS little by little in the reacting solution reported in this paper could dramatically improve the bending efficien-

This strategy is particularly useful in the present study for conjugation of 2-DG to the surface of nanoparticles through the reaction between carboxylic acid and amino group.

There are no significant difference between the TEM image of $\gamma$-Fe$_2$O$_3$-DMSA NPs and $\gamma$-Fe$_2$O$_3$-DMSA-DG NPs. It indicates no further aggregation happened during the conjugation process, which has also been confirmed by hydrodynamic diameter and distribution measurements. FTIR, SEM/EDS and TGA indicate 2-DG is successfully functionalized onto the surface of $\gamma$-Fe$_2$O$_3$-DMSA NPs. Considering that part of carboxyl groups of DMSA were absorbed on the surface of naked iron oxide particles, free carboxyl groups for further functionalization was limited and unknown. In this paper, the binding efficiency of 2-DG to DMSA coated maghemite nanoparticles was calculated to be about 60% based on total carboxyl groups of DMSA. Therefore, higher binding efficiency could be predicted by our analysis mentioned above.

The majority of cancers and isolated cancer cell lines overexpress the GLUT family members (32,33). In this paper, we chose the research object as Hela cells with high-level surface expression of GLUT1 (34–37). The results of the MTT assay performed in our study indicated that two SPIO NPs had lower cytotoxic effects to Hela cells in a concentration range up to 600 $\mu$g/mL as compared with the nonlabeled Hela cells, which could be further explored for biomedical applications. It was surprising that cells incubated with $\gamma$-Fe$_2$O$_3$-DMSA-DG NPs maintained a higher viability, as it seems like this NPs are promoting growth of tumor cells. Following 4–12 h incubated in cell culture medium of Hela, $\gamma$-Fe$_2$O$_3$-DMSA-DG NPs showed about 2- to 5-fold higher levels of cellular internalization than $\gamma$-Fe$_2$O$_3$-DMSA NPs. 2-DG-grafted NPs uptake was also effectively blocked by antibodies against the glucose transport protein GLUT1. Collectively, these results demonstrate specificity of $\gamma$-Fe$_2$O$_3$-DMSA-DG NPs and suggest involvement of the GLUT family of transporters in its uptake. The results of cellular uptake experiments show the novel targeted magnetic nanoprobes based on higher glucose consumption of tumor cell were successfully designed and prepared.

Spin–lattice relaxation time $T_1$ and spin-spin relaxation time $T_2$ may be shortened considerably in presence of paramagnetic species. While shortening of $T_1$ leads to an increase in signal intensity (a bright spot), shortening of $T_2$ produces broader lines with decreased intensity (a dark spot). The iron oxide-based superparamagnetic is $T_2$ relaxation-darkening contrast because of their high relaxivities and capacities to achieve $T_2$. The $T_2$ relaxation process occurred due to the exchange of energy between protons in water molecules. In the presence of an externally applied magnetic field, inhomogeneity in the magnetic field was created by magnetic nanoparticles which resulted in dephasing of the magnetic moments of protons and hence $T_2$ shortening. The results of MRI showed that $\gamma$-Fe$_2$O$_3$-DMSA-DG NPs-labeled Hela cells can be detected in vitro with a 1.5T clinical MRI scanner.

According to our preliminary results it becomes obvious that conjugation of 2-DG to $\gamma$-Fe$_2$O$_3$-DMSA NPs could significantly increase most tumor cells uptake of iron oxide NPs. These novel magnetic nanoparticles may allow separating, diagnosing, monitoring and treating many tumors which have been shown to overexpress facilitated glucose transporters.

### CONCLUSION

In this study, we reported a modified preparation and systematically studied the structure, magnetic and other properties of $\gamma$-Fe$_2$O$_3$-DMSA-DG NPs. 2-DG-grafted nanoparticles showed little cytotoxic effects, significant amount of...
uptake in HeLa cells and T2 contrast enhancement compared to their non-targeted counterparts. Therefore, we conclude that 2-DG-grafted γ-Fe2O3-DMSA NPs are useful as a multifunctional tumor-targeted SPIO NPs for follow-up applications in the field of magnetic cell separation, MRI, hyperthermia, drug delivery and gene therapy.
